

Name: Kapadia Dhruv T.

## Schools

1.

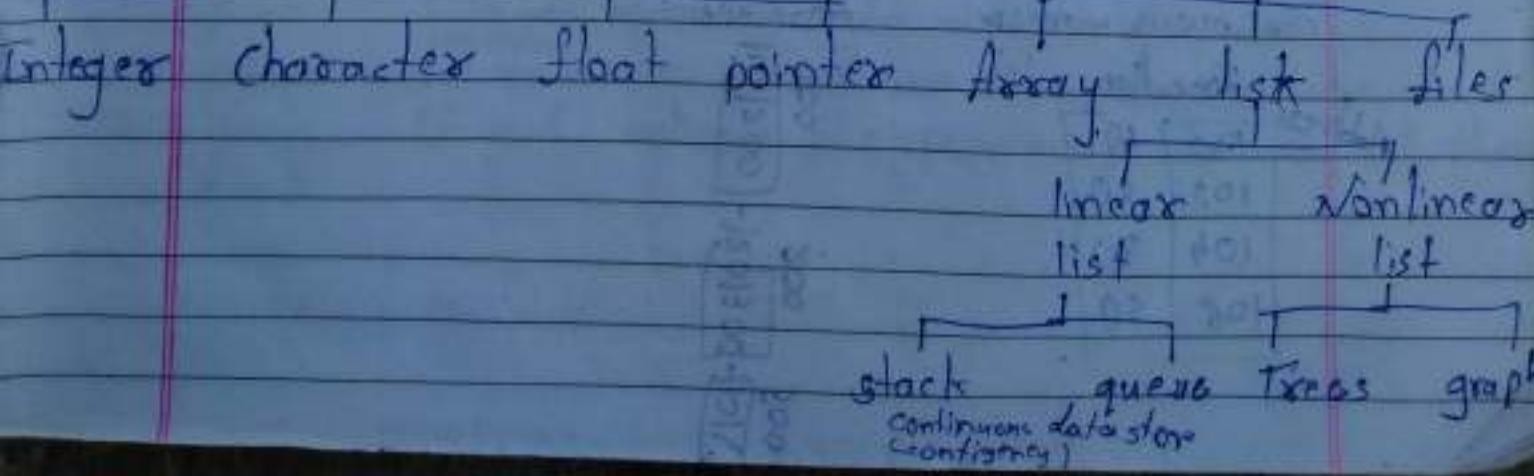

- \* Data structure is a particular way of organising data in a computer. So it can be used efficiently.
- \* There are two types of data structure:
  - primitive datastructure
  - non-primitive "
- \* Primitive Datastructure - P.D are provided by programming language as a basic building blocks. These are also known as built-in type or basic type
- \* Non-primitive Datastructure - The datastructure which is derived from primitive data-structure or primary data structure are known N.P.D

Ex:- Array, stack, que, linklist, graph, tree, structure, union & files

## Data Structures

### Primitive

D.S

- Non-primitive D.S are also known as Abstract D.S or Abstract Data type.

Notes - \* All datastructure allow us to perform different operation on data! we select this D.S based on which type of operation is required

\* There are <sup>(D.S)</sup> 2 types of D.S.

= linear D.S  
- Non linear D.S

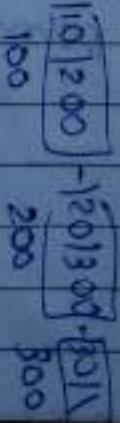

## Data structure

Linear  
D.S

Sequential  
Organization  
(array, stack,  
queue)  
continuous memory  
location  
Address

100	10
102	30
104	70
106	50

linked  
organization  
(linked list)  
random  
addressing  
store area 1

Non-linear  
D.S

Hier-  
archical  
relationship  
(Trees)  
Network  
relationship  
(graphs)

## \* linear D.S.

In L.D.S. the elements are stored in sequential order it means if we know the address of first data item then we can get the second one and so on

- \* Sequential Organization: In S.O. element occupied continuous or contiguous memory location
- \* linked list : It In this D.S. components are exist in a certain sequence but they are not necessarily stored in contiguous memory location
  - It uses a pointer which shows the relationship between the element with the help of links
  - Stack follows a concept of LIFO (last in first out).
  - Stack can be represented as a linear array.
  - Every stack has a variable TOP associated with it.
  - TOP is used to store the address of top most element of the stack. It is this position from where the element will be added or deleted.
  - Stack has three basic operations
    - (i) push - insert element into stack
    - (ii) pop - <sup>(remove)</sup> delete " from the top of the stack
    - (iii) peek - It will indicate the topmost element of the stack

Overflow condition:  $TOP \geq \max$   $TOP = \max - 1$   
Underflow :  $TOP = 0$  or  $TOP = -1$

#### \* Disadvantages:

- slow access to the other element
- memory wastage.

#### \* Application:

(i) Reverse a string (word)

(ii) conversion of expression infix to prefix to  
infix to postfix +  
postfix to infix

prefix to infix

(iii) parsing

#### \* Queue:

- Queue is a FIFO data structure in which the element that was inserted first is the first one to be taken out.
- The elements in a queue are added one end called rear & removed from the other end called front

#### \* Two operations perform:

Enqueue - insert, adding

dequeue - deleting, remove

#### \* Three Types of queues:

(i) Simple queue  $\rightarrow \text{max} > \text{front} < \text{rear}$  (ii) double ended queue

(iii) Circular queue  $f = r = 1$

$\rightarrow \text{max} > \text{front} < \text{rear} = 0$  (empty)

## \* Application:-

- pointer
- people checkout from supermarket
- call center, phone system
- CPU task scheduling
- Intruders are handled in the same order as they come

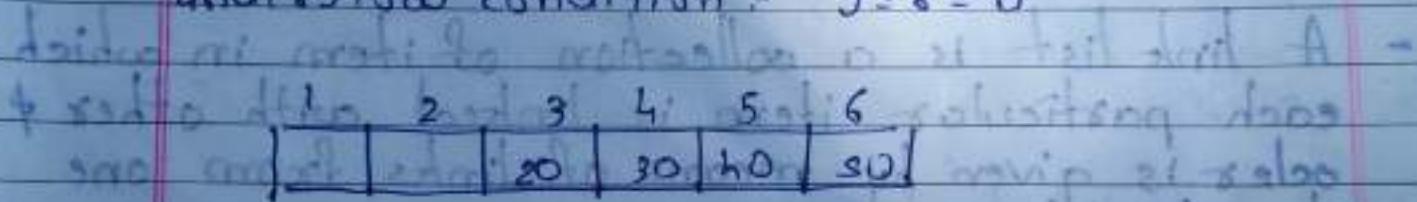

## \* Disadvantages:-

- slow access to the other item

## Circular queue

overflow condition :-  $f = l \& r > max$

underflow condition :-  $f = r = 0$

## \* linked list

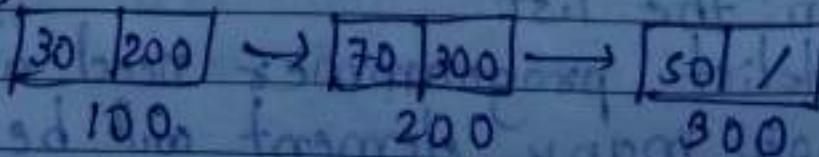

⇒ 3 types of linked list.

- singly linked list
- doubly "
- circular "

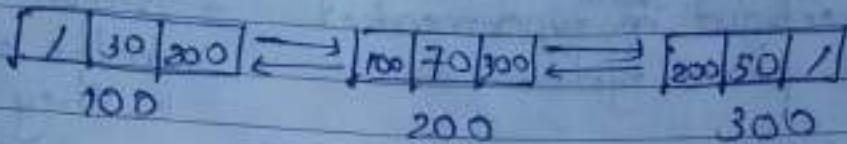

There are 2 parts

- nodes part
- Address "

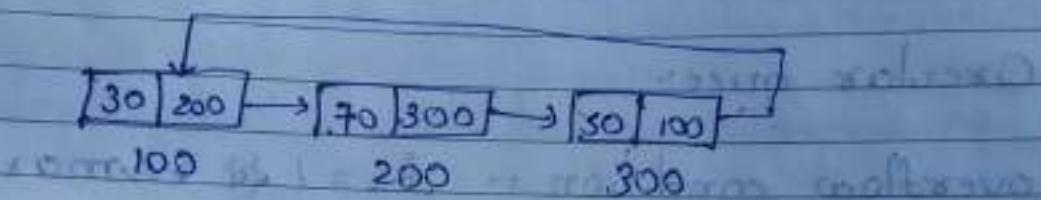

## (i) Singly linked list

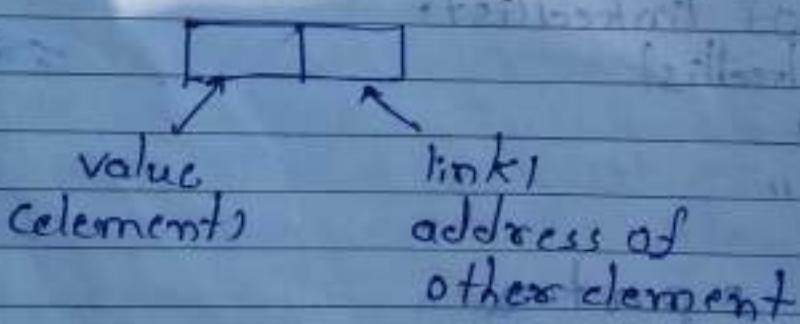

(ii) doubly linked list:-

(iii) Circular linked list:-

- A link list is a collection of item in which each particular item is linked with other & order is given by means of links from one item to other.
- Each item is denoted by node. which consist of two field

Advantages:-

- It is a dynamic data structure in which the element can be added or deleted from anywhere in the list.
- In linklist programmer need not worry about how many element will be stored in

linked list.

- In LL each element is allocated memory as it is added to the linked list.

Application:-

- It is used to implement stack, queue, tree, graph.

\* Disadvantages:-

- slow search operation & require more memory.
- reverse traversing is difficult.

Forces:-

- It is a non-Linear Datastructure in which data item called as node are arranged in some sequence.

Advantages:-

- Item can be located very quickly in tree.
- Insertion is easy.

\* Disadvantages:-

- Deletion algorithm is complex

Application:-

- telephone directory assistant information stored in tree so name & no. can be quickly find out.

## Graph

- Graph is basically a collection of vertices & edges that connect these vertices.
- It is a generalization of tree structure where instead of having purely parent to child relation any kind of complex relation b/w vertices can be depicted.
- Graph doesn't have any root node. Every node in the graph connected with other node.
- Tree has a constraint that node can have many children but only one parent. But graph doesn't have any restriction.

## Applications:

- nodes can be represent city & edges can represent the road CT can be used in GPS.
- A graph can also use to represent a comp. network where nodes are workstation & edges are its connection CT can be used in work station.

## Disadvantages:

Algorithms are slow & very complex.

## \* Performance Analysis :- select best algorithm

- Performance analysis of an algorithm is the process of calculating a space required by the algorithm & time required by the algorithm
- Performance analysis of an algorithm is performed by using the following measure.
  - i) spec space required to complete the task of ~~that~~ <sup>an</sup> algorithm.
  - ii) time required " " " " the algorithm

## \* Space complexity:

- Total amount of computer memory required by an algorithm to complete its execution is called as s.c. of that algorithm.
- For any algorithm memory requires for following purposes:
  - i) memory required to store programme/instruction
  - ii) " " " " constant value & variable value.  
e.g.  $a = 10$ ,  $a = i$

## Example:

`int square (int a)` a require 2 bytes

{  
    `return a * a;` return " " 2 bytes  
}

constant space  
complexity

`int a = 10`  
 $a = 100 \times 10$  } bytes = 4

```
int sum( int A[], int n )
```

```
{  
    int sum=0, i;  
    for ( i=0; i<n; i++ )  
        sum = sum + A[i];  
    return sum;  
}
```

```
sum = sum + A[i];
```

```
return sum;
```

4

Algorithm to find sum of all elements of array  
and input values

## Time complexity : (T.C)

The T.C of that algorithm is the total amount of time required by an algorithm to complete its execution.

- To calculate the 'T.C' we check only how our program is behaving for the different input values to perform all the operation like arithmetic, logical, relational, conditional, Assignment, operation, return values etc.
- If any program require fix amount of time for all its values then its time complexity is said to be constant time complexity.
- If the amount of time required by an algorithm is increased with the increase of its values then that time complexity said to be Linear T.C.

best case =  $\omega$   
average

# Asymptotic notation of algorithm is a mathematical representation of complexity.

- c1) Big - oh (O) ~~monotically increasing~~ worst case
- c2) Big - omega ( $\Omega$ ) ~~best~~ case
- c3) Big - theta ( $\Theta$ ) Average case

## \* Big-O:

- Big-O notation always indicates maximun time required by algorithm which describes the worst case of any time complexity.

$$\text{time}(f(n)) = \Theta(g(n))$$

actual time  $\leq$   $\frac{\text{max time}}{\text{min time}}$   $\leq C * g(n)$  where  $C = \frac{\text{max time}}{\text{min time}}$

$$f(n) = \text{algorithm's time} \Rightarrow n \rightarrow n_0$$

goal: arbitrary  $T(n)$  you can trying to reduce it to your algos.

$f = \text{Some algo} \mid \text{algorithm}$

$$f(n)$$

mo

$$f(n) = \Omega(g(n))$$

general linear min types  
 $f(n) \geq c + g(n)$

alg.  $f(n) = \text{algo. refun } n_2, n_0$   
 $g(n) = \text{obj. time complexity}$  You are  
paying it actual time to your algo.

$c = \text{some real constn}$

$$f(n)$$

$n_0$

This always indicate min time required  
by alg. which desirble. The ~~more expensive best~~  
case of an algo. time complexity,

Big - O

$$f(n) = O(g(n))$$

constant  $c, g(n) \leq f(n) \leq C_2 * g(n)$   
 $O \leq C, g(n) \leq f(n) \leq C_2 * g(n)$

$f(n) = \text{algo. run time } n_2, n_0$   
 $g(n) = \text{obj. time complexity}$  you are  
 $C, c = \text{some real constn}$

$$c_1 + g(n)$$

2.

Time complexity:

Example:

$f(n)$ )

$\sum_{i=1}^n i + \text{all calc}$   
pt of "Hello" in

$y = \underline{\underline{1+n+n+n}} = \underline{\underline{3n+2}}$

$O(n^2)$

Below of n time each  
task complete each

```
function()
{
    for(i=1; i<=n; i+=1)
        p1("Hello"); n/2+1
}
```

```
3n + 5 = O(n)
```

```
for(i=1; i<n; i++)
    for(j=1; j<n; j++)
        p1("Hello")
```

~~Size~~ =  $O(n^3)$

# Queue

(i.) Simple

Insertion of element in simple queue:

Insert Algorithm (ENQUEUE)

Procedure QINSERT (Q, A, F, N, Y)

F & R = It is a pointer which points to front & rear element of queue

Q = Queue

N = Number of elements in queue. Size of queue

y = element to be inserted

(i) [Overflow]

if  $R \geq N$   
then write (overflow)  
Return

(ii) [Increment rear pointer]

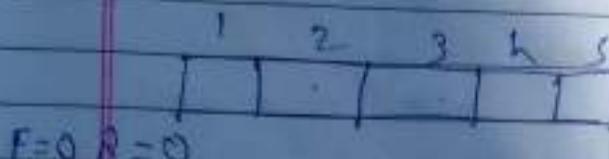

$R \leftarrow R + 1$

(iii) [Insert Element]  
 $Q[R] \leftarrow y$

(iv) [Is front pointer set?]  
if  $F = 0$

then  $F \leftarrow 1$   
Return

(i)  $N = 5$

(ii)  $y = 10$

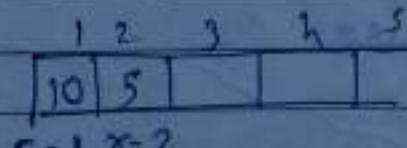

$$\begin{aligned} &x \geq 5 \\ &0 \geq 5 \text{ false} \\ \Rightarrow &x = x + 1 \end{aligned}$$

$$x = 1$$

$$\Rightarrow 2 \times 17 = 10 \quad \Rightarrow \quad F = 0 \Rightarrow \underline{\underline{F = 1}}$$

(iii) Insert  $y = 5$

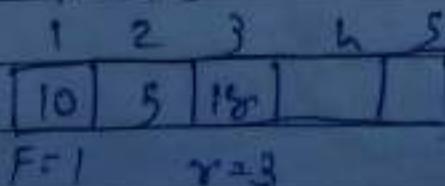

$$\Rightarrow x \geq N \Rightarrow 1 \geq 5 \text{ false}$$

$$\Rightarrow \underline{\underline{x = 2}}$$

$$\Rightarrow 2 \times 27 = 5$$

$$\Rightarrow f = 1 \Rightarrow \text{false}$$

(iv) Insert  $y = 18$

$3 > 5$  false  
 $\Rightarrow x = x + 1 = 4$   
 $\Rightarrow 2[4] = 20$   
 $\Rightarrow f = 1$  false

as Insert  $y = 25$

1	2	3	4	5
10	5	18	20	25

$f=1$        $x=5$

$x \geq N$   
 $\Rightarrow 4 > 5$  false  
 $\Rightarrow x = 5$   
 $\Rightarrow 2[5] = 25$   
 $\Rightarrow f = 1 \Rightarrow$  false

cvi.)

$x \geq N$   
 $5 \geq 5 \Rightarrow$  True  
overflow

## DELETE Algorithm (Dequeue)

Procedure QDELETE (Q, F, R)

F & R = It is a pointer which points to front &  
rear elements of Queue

Q = Queue

y = temporary variable

[Underflow ?]

if  $F = 0$       ( $F = -1$ )      starts with 0  
then write ('UNDERFLOW')  
RETURN/0

Q1

Consider the simple queue given below with four memory cell which has front & rear pointers zero.

draw the simple queue structure and represent the position of front & rear object for each of the following operation

Insert A, B, C

Delete A, B

Insert D, E

2, 3

$$x = 3$$

$$\alpha[3] = C$$

1	2	3	4
A	B	C	

$$F = 1$$

$$R = 3$$

$$F \neq 0$$

$$\Rightarrow \cancel{x \neq F} \quad y = \alpha[F]$$

$$y = \alpha[1]$$

$$y = A$$

$$F = 0 \Rightarrow F \neq R$$

$$\Rightarrow F = 2$$

1	2	3	4
	B	C	

$F = 2 \quad R = 3$

$$y = \alpha[2]$$

$$y = B$$

$$F \neq R$$

1	2	3	4
		C	

$$F = 3$$

$$R = 3$$

~~3 > 4~~

$$x = 4$$

$$y = \alpha[4]$$

$$y = D$$

1	2	3	4
	C	D	

$$F = 3 \quad R = 4$$

4 > 4 condition true  
condition overflow.

~~If queue starting from 0 then~~  
~~Overflow condition  $\Rightarrow \max - 1$~~   
 ~~$F = -1$~~

## \* Priority Queue:

- It means Priority Queue is an abstract data structure in which each element is assigned a priority.
- The priority of the element will be used to determine the order in which this element will be processed.
- The general rule of processing the element in P.Q is:
  - (i) the element with higher priority is processed before an " " with lower priority
  - (ii) two elements with same " " are processed on a first come first serve basis
  - (iii) ~~It is~~
  - (iv) It is a queue in which we are able to insert or remove item from any position based on some priority. It is often referred to as a priority queue.
  - (v) P.Q are widely used in O.S to execute the highest priority task first.

## Implementation of priority queue

- insertion order  
deletion order
- (i) Inserted list: elements stored in sort order.
  - (ii) Unsorted list:

sorted list      (ii) unsorted list

Insertion O(n)      Deletion O(n)  
deletion O(n)      Insertion O(n)

5	10	15	20	10
---	----	----	----	----

This can be implemented using linked list :-

$R_1$	$B_2$	$\dots$	$R_{i-1}$	$O_i$	$O_2$	$\dots$	$O_{j-1}$	$B_1$	$B_2$	$\dots$	$B_k$
1	1	...	1	2	2	...	2	3	3	...	3

$R_i$        $O_j$

Priority 1       $R_1, R_2, \dots, R_{i-1}, \dots, R_i, O_j, \dots$

Priority 2       $O_i, O_2, \dots, O_{j-1}, \dots, O_j$

Priority 3       $B_1, B_2, \dots, B_{k-1}, B_k$

90	1	350	10	1	350	10	1	350	10	1	350
----	---	-----	----	---	-----	----	---	-----	----	---	-----

In a single sequential storage structure is for the priority queue. The insertion of an element must be placed in the middle of. This can require a movement of several elements.

It is better to split the RL into class each having its own storage structure.

A very representation of priority queue is

Potency	Root	Score
1		3
2		1
3		4
4		4
5	A	9
6	B	2
7	C	3
8	D	5
9	E	3
10	F	1
11	G	9
12	H	1
13	I	9
14	J	1

Priority: 3 L

To insert a new element with priority 3 at the element

## Delete:

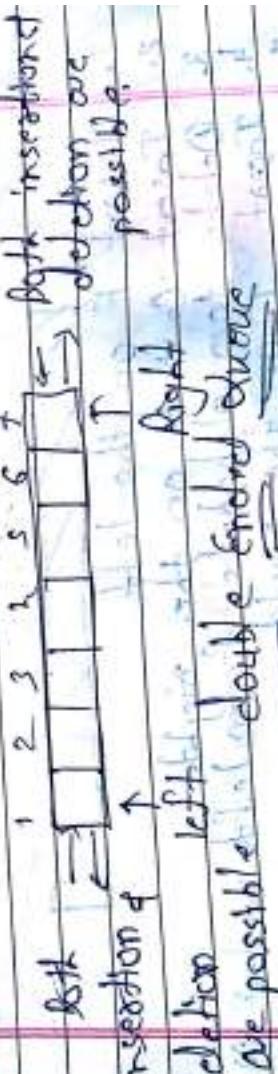

To delete an element we have to find the first non empty queue and then process the second element of first ~~a~~ non empty queue.

## \* Dequeue Double ended queue

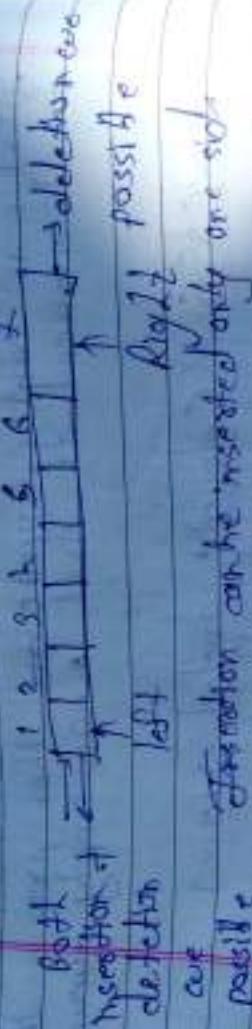

- A dequeue is a linear list of elements which element may be inserted & deleted from both ends.
- It's also known as head tail linked list, because element can be deleted & inserted from both ends.
- A element can be deleted & deleted from both ends.
- To compute memory dequeue is implemented as array or doubly linked list.

There are two types of dequeues:

- (i) input restricted dequeue
- (ii) output restricted dequeue

c) Input restricted

iii) Output restricted

- \* Consider a Q given below with 10 memory cells which has  $left = 1$  &  $right = 5$ . Discuss the structure of representation of the position of left and right pointers for each of the following operations

1. Insert F on the left
2. Insert G & H on the right
3. Delete two alphabets from left
4. Insert I on the right
- " J or " left
- Delete two alphabets from right

list with

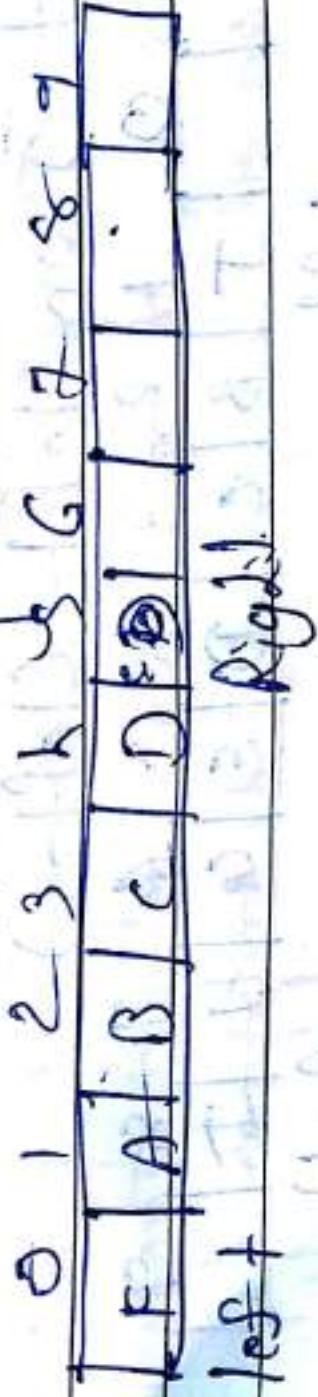

0	1	2	3	4	5	6	7	8	9
A	B	C	D	E	F	G	H	I	J

left

Right

Traversed from

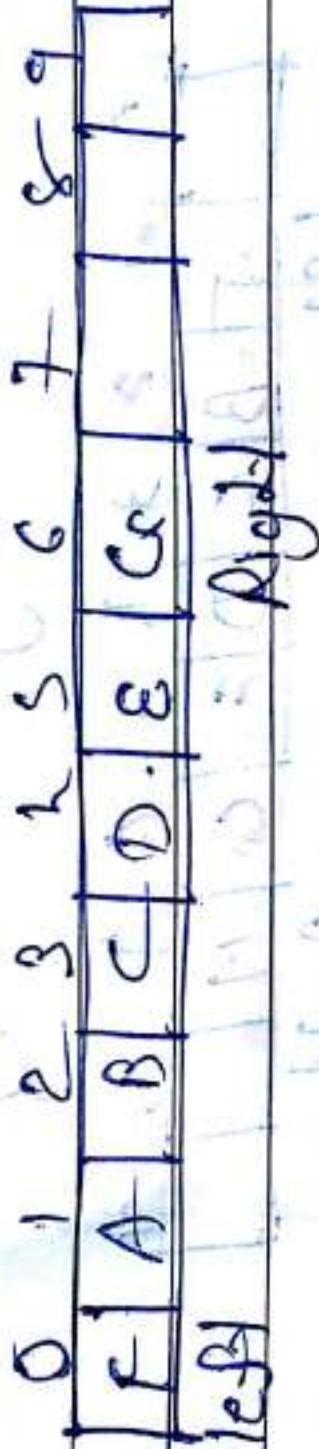

left to right implemented by J.

left

Right

Traversed on right implemented by "J".

left

Right

Traversed on right implemented by "J".

5. Insert T on right

0	1	2	3	4	5	6	7	8	9
T	B	C	D	E	A	H	I		
left								Right	

0	1	2	3	4	5	6	7	8	9
T	B	C	D	E	A	H	I		
left								Right	

6. Delete T from right (Right →)

0	1	2	3	4	5	6	7	8	9
T	B	C	D	E	A	H	I		
left								Right	

Delete H from Right (Right →)

0	1	2	3	4	5	6	7	8	9
T	B	C	D	E	A	H	I		
left								Right	

→ If there is only one element into the DS and if deletion operation is performed on left & right to zero. Or due to its start from y) else both

## \* link list:

### what is link list:

- A list is a collection of elements in which each element is linked with other and one is given by link from 1 element to another.
- Each element is denoted by node.
- List point contain the value of the node & second contain the address of next node

### Advantages of array :-

- Array is very simple to use & easy to create.
- No memory management needed.
- To access we can access any element with the help of index directly.
- Array is quick to look.

### Disadvantages of array :

- It is a static in nature, memory allocated at compile time.
- Insertion & deletion of element is more complex in comparison to link list.

### Advantages of link list :

- It is a dynamic data structure.
- The size of the linklist can grow or shrink in size during execution of the program.

In linked list ~~predecessor~~ need not ~~class~~ link  
how many element will be stored in ~~list~~  
link list each element is allocated me  
as it is added to the list.

### Disadvantages of L.L.

lot of overhead (lots of malloc call & pair  
assignment) (time consume more)  
we have to traverse the entire list to go  
end node  
it consume extra space to contain the address  
of the next node.

### Applications of L.L.

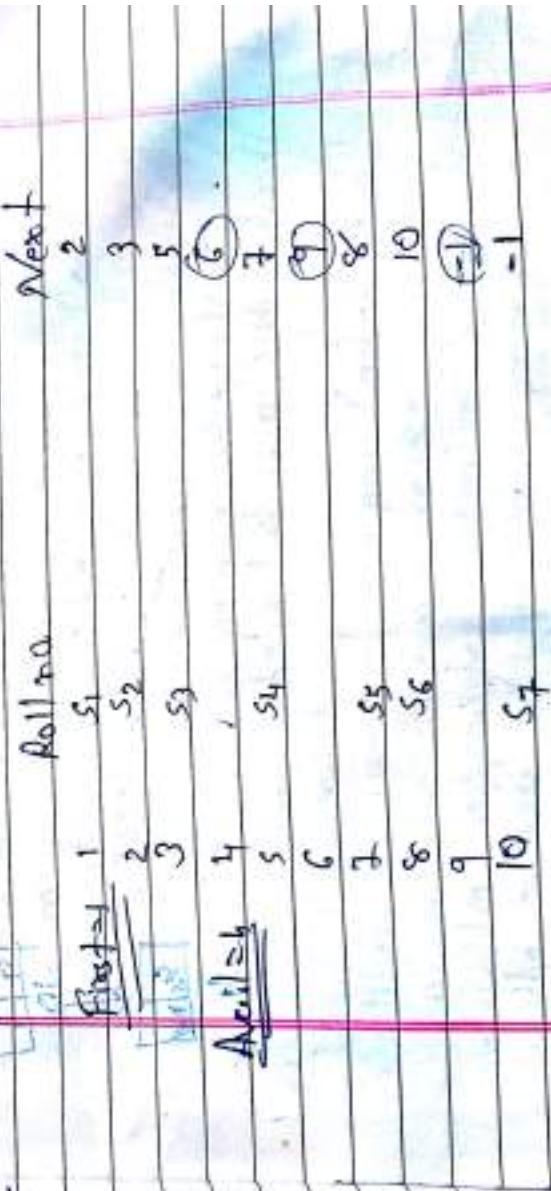

To implement stack, queue, graph, tree etc  
implemented using L.L.  
Consider the history section of web browser  
it creates the link list of web pages visited  
so when you press the back button the prev  
page is loaded

\* Representation of linklist in memory

memory

Representation

When we delete a node from a linklist then operating system changes status of the memory occupied by that node from memory available.

Computer maintains a list of all the free memory cells.

The list of available space is called as free pool.

linklist has a pointer variable which stores the address of the first node of the linklist.

Likewise for the free pool (which is a linklist of all the free memory cell)

- You suppose now when new student ~~comes~~ comes to be added when a memory add. is pointed by avail will be taken & use to store the information.
  - After the insertion next available free space add. will be stored in avail.
- \* If we delete a node space occupied by that node must be given back to the free pool so memory can be ~~use~~ reuse by other program.
- The operating system does this task of adding free memory to the free pool.
  - This task perform by O.S when it finds the CPU either or the programme are in a short of memory space.
  - The O.S. scan through all the memory cell & mark those cell that are being use by some other program.
  - It collects all the cells which are not being use and add their address to free pool.
  - o This process is called as garbage collection.

## Algorithm

a) Simply linked

\* A.A. A for insert a node at beginning.

Insert at beginning :-

FRST = INSERT(X, FRST);

X = new element which is to be inserted  
frst = a pointer to the first element of linked list  
in which node contain info and link point  
avail = pointer to the top element of the availability of stack.  
new = temporary variables.

Procedure :-

[check overflow]

new = 200

if AVAIL = NULL  
then write ('AVAILABILITY STACK UNDERFLOW')  
Return (frst)

(obtain address of next free space)

New ← Avail

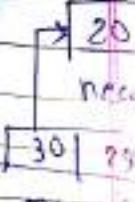

[remove free node from availability stack]

Avail ← LNK(Avail)

4. [Initialize fields of near node & its links to the list]

INFO(CNEW)  $\leftarrow$  x

Binary search tree also known as ordered binary tree in which nodes are arranged in order.

In a binary search tree all the nodes in the left sub tree have a value less than ~~or greater than~~ of root node correspondingly all the value in a right sub tree have a value either equal to or greater than root node.

Same rule is applicable to every sub tree in a given tree

root node

Operations on BST:

Searching: Algorithm

(NODE → pointer  
any node)

search (NODE, VAL)

Step 1 If NODE = NULL then

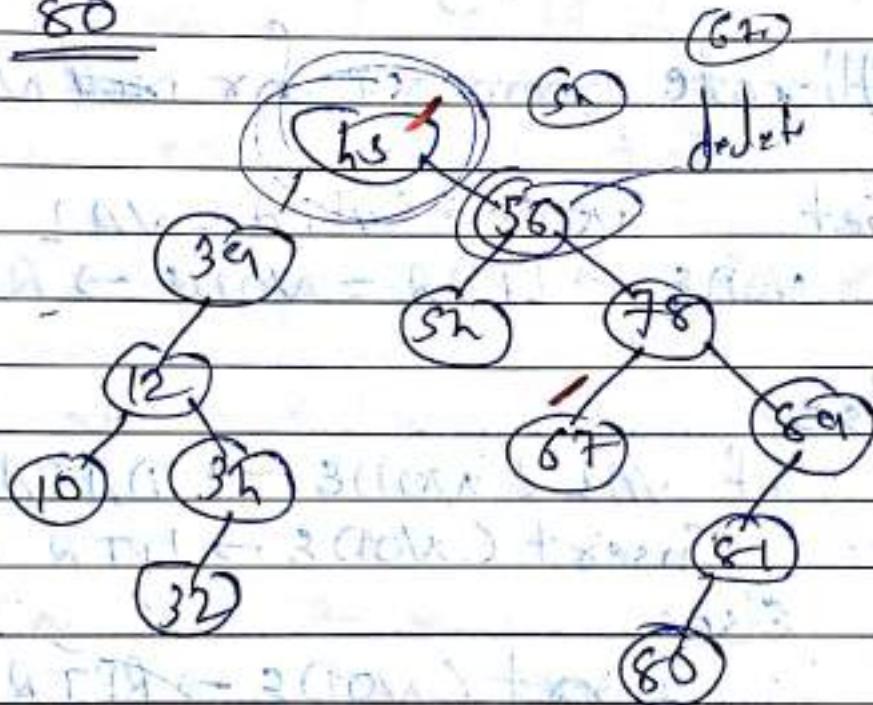

write ("Empty tree")

Else if  $\text{NODE} \rightarrow \text{DATA} > \text{VAL}$   
call search( $\text{NODE} \rightarrow \text{LPTR}$ ,  $\text{VAL}$ )

Else  $\text{if } \text{NODE} \rightarrow \text{DATA} < \text{VAL}$   
call search( $\text{NODE} \rightarrow \text{RPTR}$ ,  $\text{VAL}$ )

END

Insert 80

10, 12, 32, 39, 5, 51, 56, 67, 78, 89

## Operations on BST

### Inserting Algorithm

Insert (NODE, val)

Step 1 If NODE = NULL then

    write ("empty tree")

Allocate memory for node NODE

Set NODE → DATA = VAL

NODE → L PTR = NODE → R PTR = NULL

Else:

    if VAL < NODE → DATA

        Insert (NODE → L PTR, VAL)

    Else

        Insert (NODE → R PTR, VAL)

Step 2

END

### Deletion ::

To delete the node from BST following cases  
are to be consider:

CASE 1: Deleting a node that has no child

In this case node can be deleted by setting its parent pointer to NULL.

### CASE 2: Deleting a node with one child

In this case replace the node with his child.

If the node was left child of its parent then child also become a left child.

If the node was right child of the parent then child also become the right child.

### CASE 3: Deleting a node with two child

The node is replace with its inorder predecessor (right most child of left sub tree) or inorder successor (left most child of Right sub tree).

Delete (NODE, VAL)

Algorithm:

Step 1 If  $\text{NODE} = \text{NULL}$  then  
write "Value is not found in TREE".

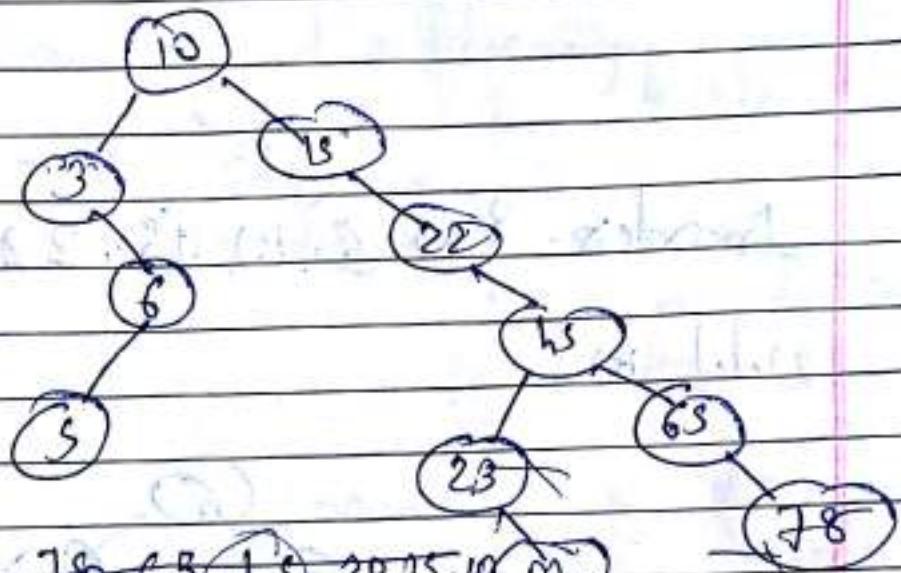

Else If  $\text{VAL} < \text{NODE} \rightarrow \text{DATA}$   
Delete ( $\text{NODE} \rightarrow \text{LPTA}$ ,  $\text{VAL}$ )

Else If  $\text{VAL} > \text{NODE} \rightarrow \text{DATA}$   
Delete ( $\text{NODE} \rightarrow \text{RPTA}$ ,  $\text{VAL}$ )

If  $\text{NODE} \rightarrow \text{LPTR} = \text{NULL}$  AND  
 $\text{NODE} \rightarrow \text{RPTR} = \text{NULL}$   
SET  $\text{NODE} = \text{NULL}$   
Else If  $\text{NODE} \rightarrow \text{LPTR} \neq \text{NULL}$   
SET  $\text{NODE} = \text{NODE} \rightarrow \text{LPTR}$   
Else  
SET  $\text{NODE} = \text{NODE} \rightarrow \text{RPTR}$   
[~~AND~~ END OF IF]  
End

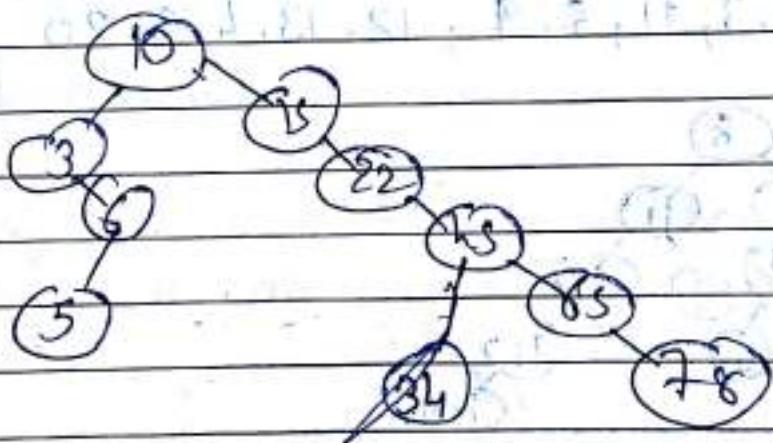

Example:-

• Integer  
• Character  
• Real  
• Boolean  
• String

Non-Primitive

Linear  
arrays,  
stack,  
queue  
Non-linear  
trees,  
graphs  
linked list

## Application of Array:

- Arrays are frequently used in C, as they have a number of useful applications. These applications are:
  - Arrays are widely used to implement mathematical vectors, matrices, and other kinds of rectangular tables.
  - Many database include one 1-D arrays whose elements are records.
  - Arrays are also used to implement other data structures.

$$L(A_i) = \text{base} + \text{element size} * (\text{element position} - \text{lower bound})$$

### Stack

## 2. Towers of Hanoi :-

Given  $n$  discs of decreasing size stacks on one pedestal & given two empty pedestal.

It is required to stack all the disc onto destination pedestal in decreasing order of size.

### Rules

1. Only 1 disc may be moved at a time.
2. A disc may be moved from any pedestal to any other pedestal.

3. At no time may a longer disc rest upon a smaller disc.

Solution for move n discs from middle A to C.

1. move  $n-1$  disc from A to B
2. move disc n from A to C
3. move disc  $n-1$  from B to C

Algorithm:- (Tours of Hanoi)

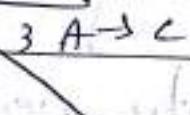

Hanoi (disc, A, C, B) generalized form

```

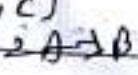

if (disc == 1)
    move disc from A to C
else
    Hanoi (disc-1, A, B, C)
    move disc from A to C
    Hanoi (disc-1, B, C, A)

lower bound = 0

# Non-Linear Data Structure

\* Tree:

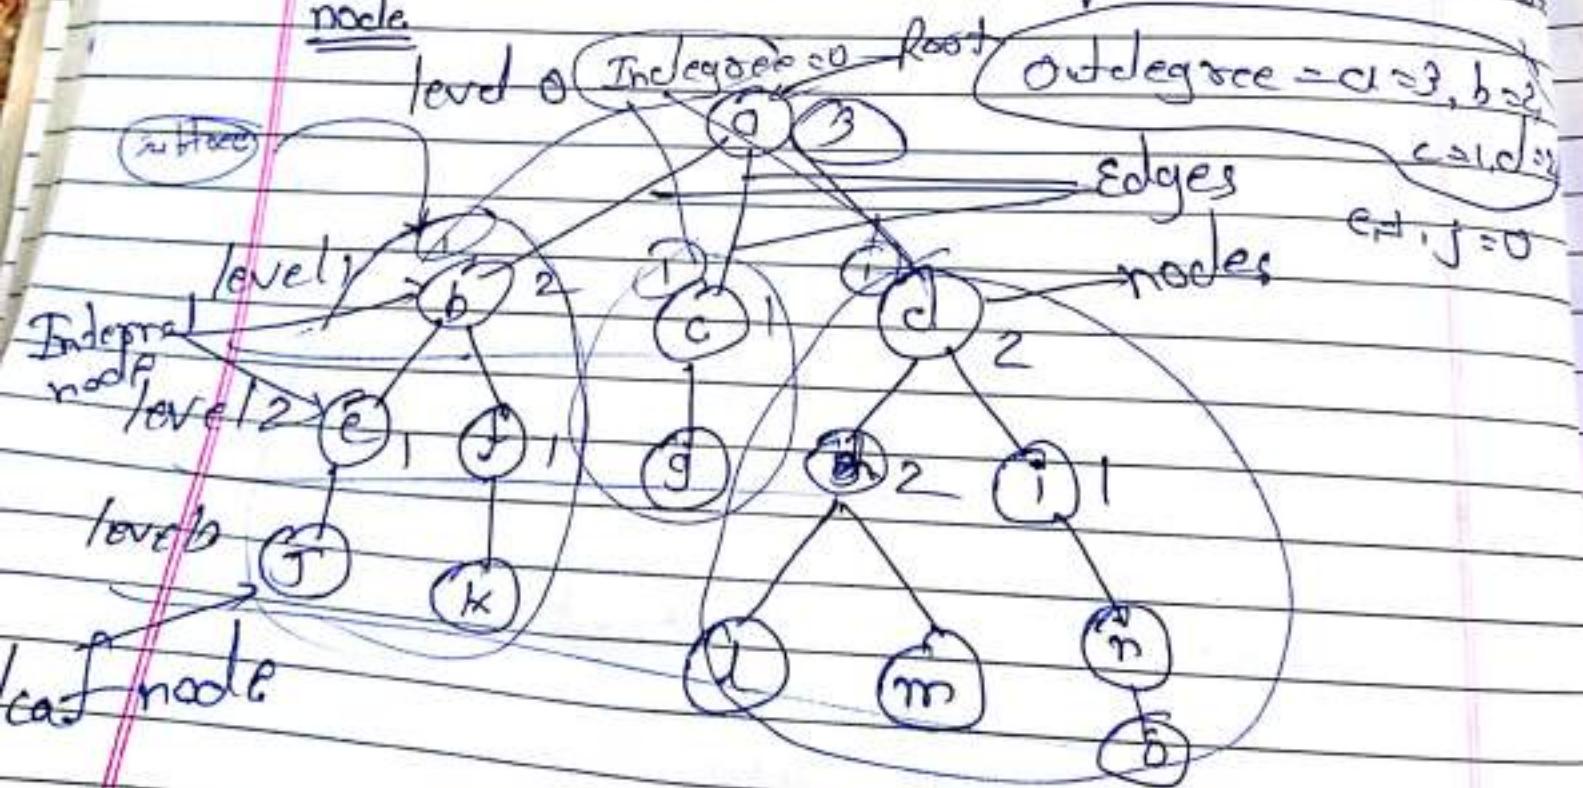

- A tree is a non-primitive, non-linear data structure made up of nodes & vertices & edges without having any cycle.

key terms:

⇒ Node:

⇒ Each element in hierarchical representation is called node.

→ Edges (link)

Connecting link b/w two node is called edges.

$$\text{node} = 12 = n$$

$$\text{edges} = 14 = n - 1$$

If no. of node is  $n$  in tree then there will be max  $n-1$  edges.

→ Root node:

It is a specially design first node in the hierarchical represent of the tree.

Root node for given tree = a

→ level of node:

Level of any node is the length of its parent path from root node.

→ Root node is at level 0, because root has 0 distance from its self.

- Every child node level. is defined as parent no.

Degree of node :-

⇒ No. of children of node is called the degree of node.

- degree of  $a=3, b=2, c=1, d=2, \dots$

⇒ Indegree : Indegree of a node is the no. of edges arriving at node.

root has Indegree 0.

⇒ Indegree  $b=c=d=1$

All node in tree except root node has Indegree 1.

Outdegree :- Outdegree of a node is the no. of edges leaving the node.

Outdegree  $a=3, b=2, c=1, d=2, j=0, k=0$   
 $i=l=m=n=0$

Degree of tree :- maximum degree of a node is called degree of tree.

Degree of tree = 3

\* leaf node (terminal or external node) :-

→ A node which has outdegree zero is called leaf node.

\* internal node (non-terminal or branch node)

A node with at least one child is called internal node.

\* parent : A node is a parent if it has a child successor node and outdegree  $> 0$ .

\* child : A node with parent is a child.

\* symlinks : level same, both are parent same.

Two or more node with same parent are called as symlinks.

Symlinks : b, c, d are symlinks of each other

\* path : A sequence of consecutive edges is called path.

path of m : a-b-h-m

- Subtree :- Each child from a node forms a subtree recursively.

- Ancestor :- An ancestor of a node are all the nodes along the path from the root to that node.

1 Ancestor : a, d, h  
2 " : a, b, f

\* Descendent :- A descendent of any node is all the nodes in the path from a given node to leaf node.

1 descendent : h, i, j, m, n  
2 " : e, f, i, k

\* Empty tree or null tree :- A tree with no nodes is called null or empty tree.

\* height of node :- total no. of edges from leaf node to a particular node in the longer path is called height of node.

$$\text{height of } g = 3$$

$$\text{" " " } d = 2$$

$$\text{" " " } h = 1$$

$$\text{" " " } l = 0$$

height of tree :-

height of root node is said to be height of tree.

height of tree = 4

height of d = 3

c = 1

b = 2

\* depth of node :- total no. of edges from root node to a particular node is called as a depth of a node. (level of node)

depth

a = 0

b = 1

\* depth of tree :- total no. of edges from root node to a leaf node in the longest path is said to be a depth of tree.

\* forest :- It is a group of disjoint trees.

If we removed a root node from a tree it becomes forest.

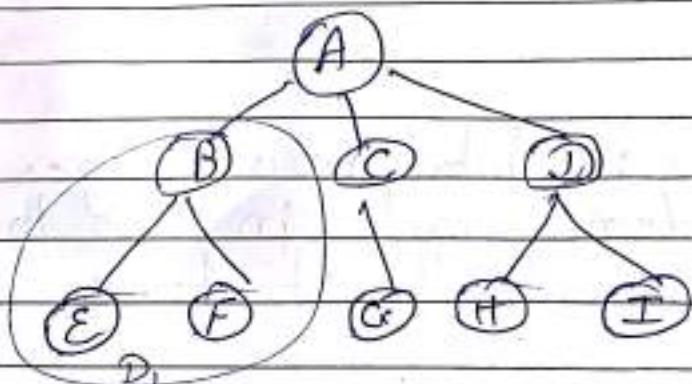

## Representation of tree

(A)

→ A tree contains one or more nodes such that one of node is called root while all other nodes are partition into a finite no. of tree called subtree.

A tree is defined in terms of:

(B, E, F), (C, G), (D, H, I)

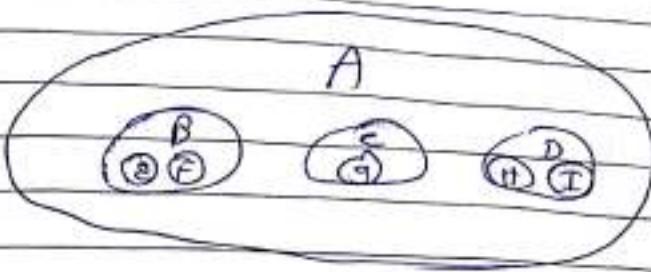

## Graphical representation of a tree :-

⇒ 4 method to represent a tree :-

- c(i) Venn diagram
- c(ii) Nesting parenthesis
- c(iii) table of content content
- c(iv) level number format

2. Venn diagram:

3. Nesting parenthesis:

(A(B(C)(E)(F))(C(G)))(D(H)(I)))

3. table of content:

\* Binary tree: A tree in which every node can have maximum of two children is called binary.

Parent / root node

## Representation of binary tree:

In computer a binary tree can be maintained either by

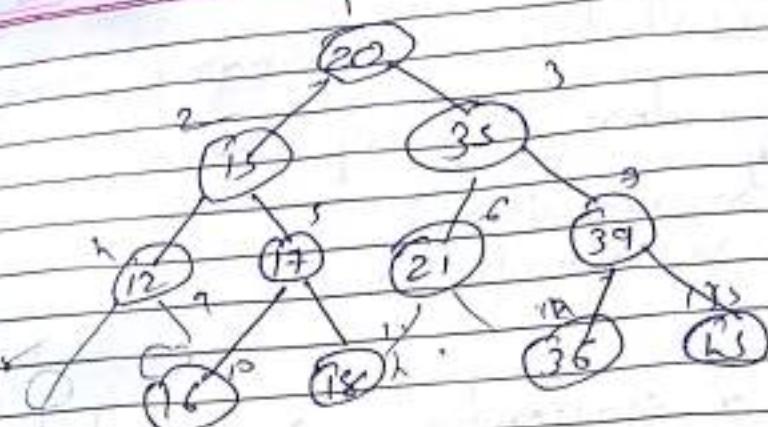

1. Array representation
2. Linked representation

### 1. Array (sequential) representation:

- We are using 1-D array to represent a binary tree.

following are the rules (array name)

- (i) 1-D array called TREE will be used.
- (ii) Root node of a tree will be stored at first location.
- (iii) children of node  $k$  will be stored in location  $2k$  &  $2k+1$ .
- (iv) maxm size of array =  $2^d - 1$  where  $d$  = depth of tree.
- (v) An empty tree or subtree is specified using null.

$$\text{max size of array} = \underline{15} (2^4 - 1)$$

1	20
2	15
3	35
4	12
5	17
6	21
7	39
8	.
9	1
10	16
11	18
12	.
13	.
14	36
15	hs

$$k=1$$

$$c_{15} \quad 2k = 2$$

$$c_{35} \quad 2k+1 = 3$$

$$k=2 \quad 18 \quad \frac{4}{5}$$

$$17 \quad \frac{5}{6}$$

$$21 = \frac{2k}{2k} = 6$$

$$39 = 2k+1 = 7$$

$$16 = 10 = 2k$$

$$18 = 11 = 2k+1$$

$$36 = 14 = 2k$$

$$hs = 15 = 2k+1$$

## linked representation of Binary tree :-

- Doubly link list is used to represent binary tree.
- It contain three part.
- i) stored in left child address.
- ii) data element (actual data)
- iii) stored in right child address.

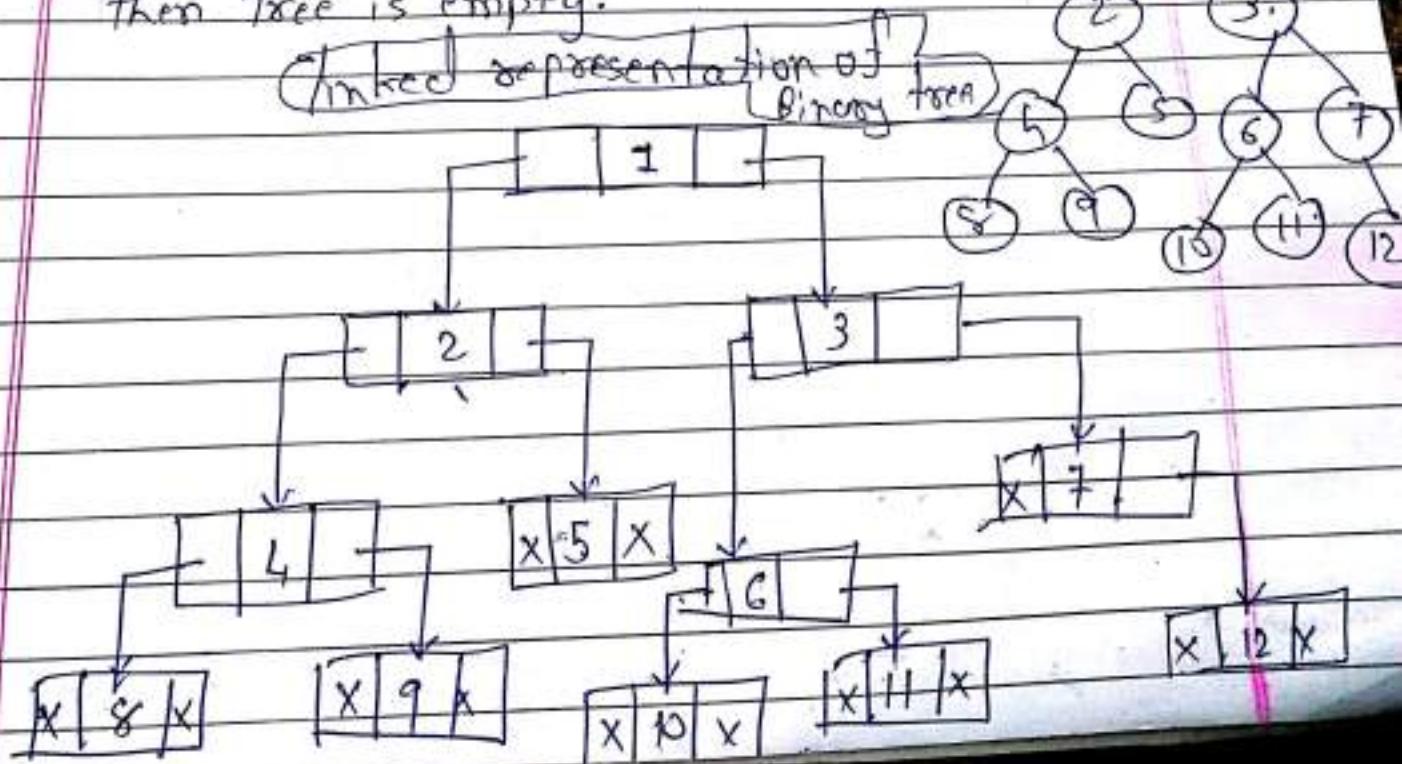

[left child] Data [right child]  
[address] [ ] [address]

Every binary tree has a pointer ROOT which point to root element of a tree.

If ROOT = NULL

then Tree is empty.

## Linked representation of Binary tree

## memory representation :-

left child  
address

Data

Right child  
address

1	4 -1	9	-1
2	6	3	8
3	5	1	2
4			
5	9	2	14
6	7	6	10
7	-1	10	-1
8	6 -1	7	11
9	12	4	-1
10	-1	10 11	-1
11	-1	12	-1
12	-1	8	-1
13		5	
14	-1		-1

(leftmost child)

\* Generate binary tree from a general tree

Step-1

The first (right node) will work as a root node.

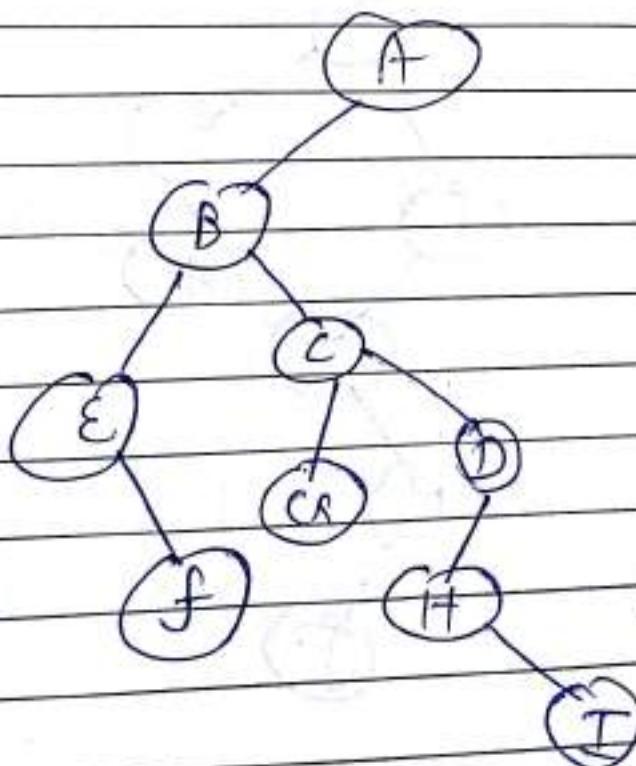

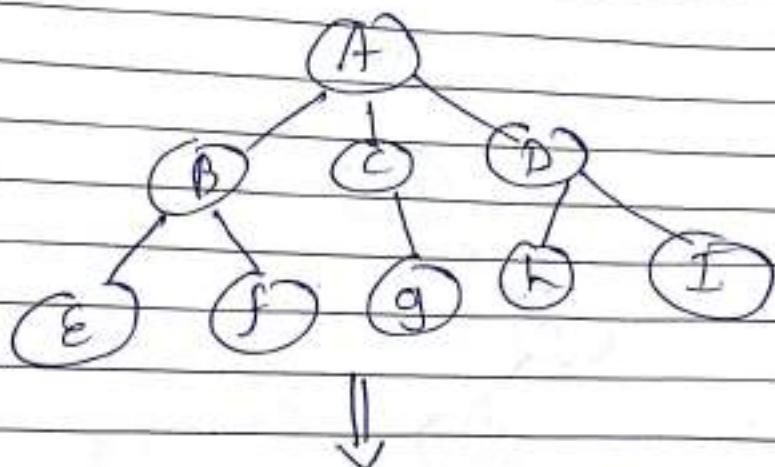

Step-2

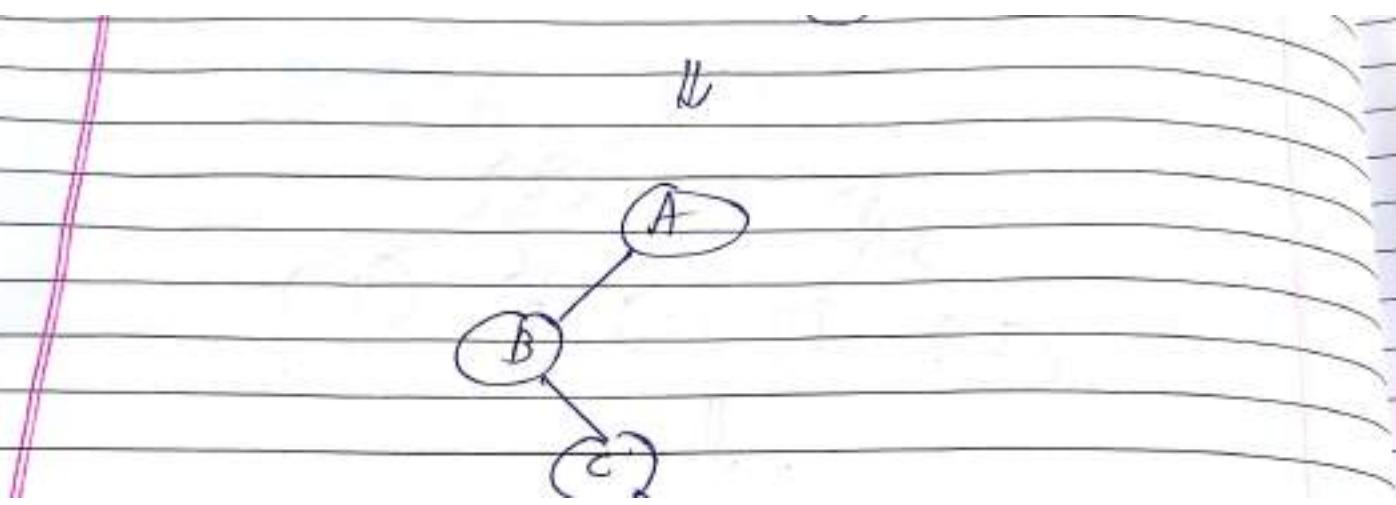

Left child of any node will be as it is.

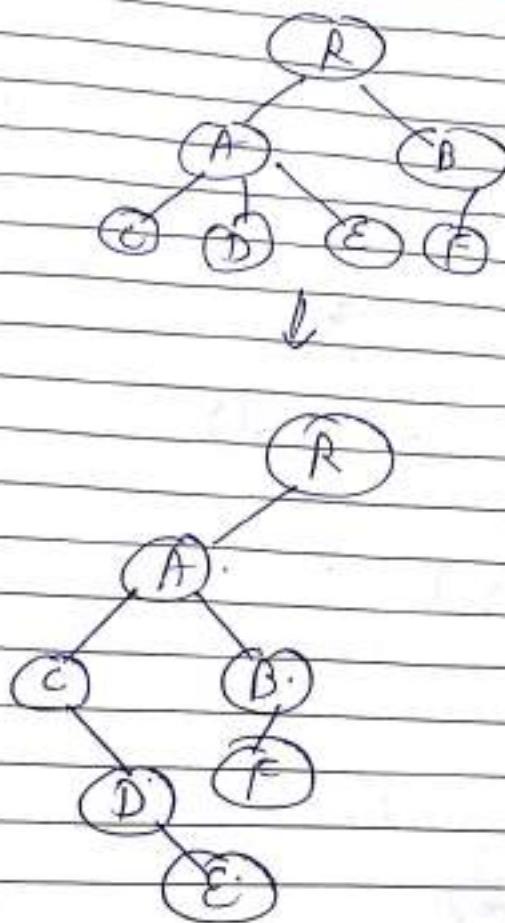

Step-3

Right child of a node will be the right child of its left sibling.

Q1

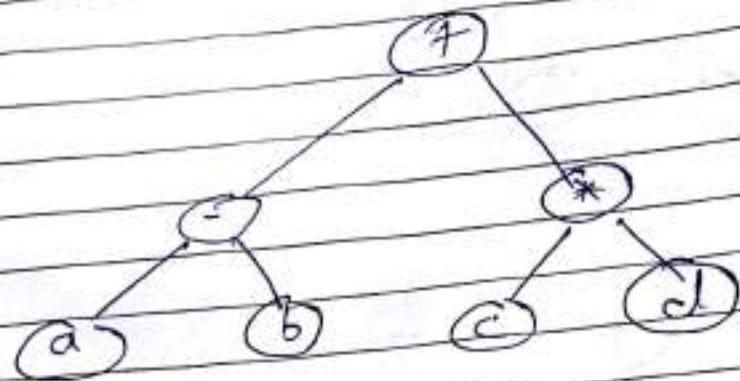

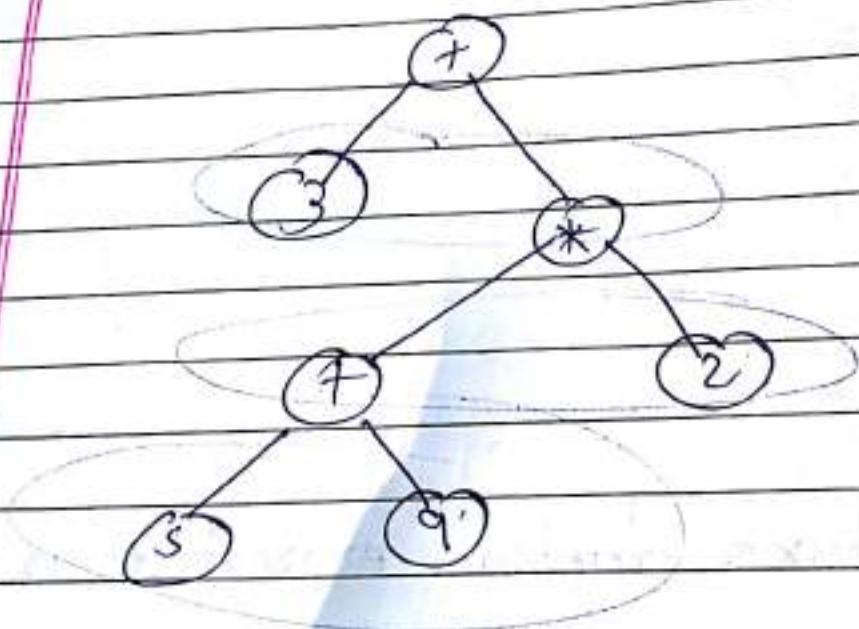

## Expression tree

- ⇒ - The tree which stores algebraic expression is called expression tree.
- All operand will be the leaf node
- All operator will be the internal node

~~1~~  $(a - b) + (c * d)$

~~2~~  $3 + (5 + 9) * 2$

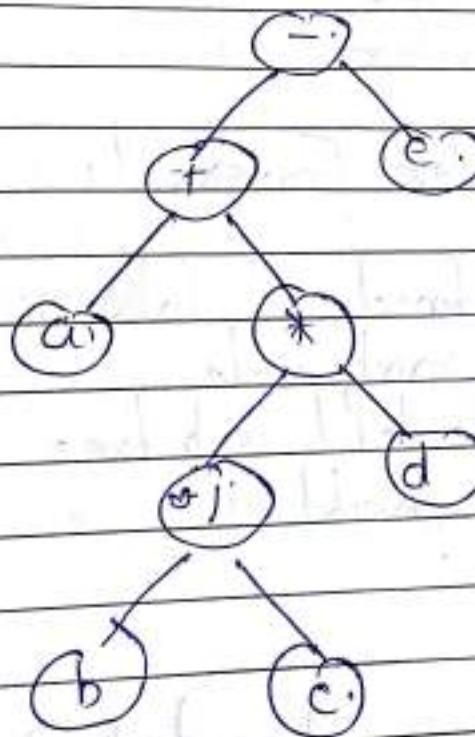

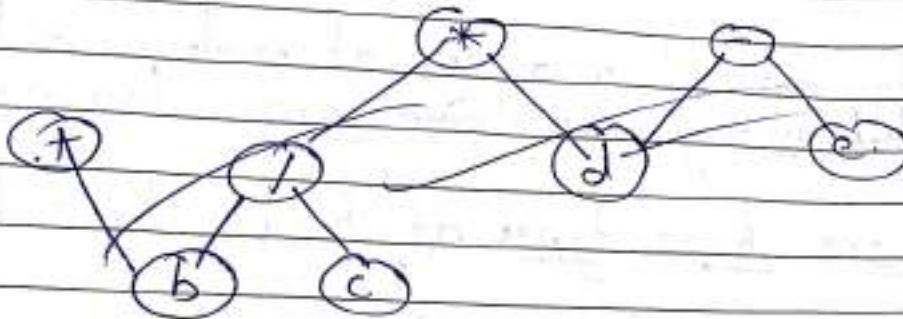

(3)

$$a + (b / c * d) - e$$

## \* Binary tree traversal:

(Traversing of binary trees)

⇒ If the process of visiting each node in a tree exactly ones in a systematic way.

Definition: Display or visiting order of node in a binary tree is called binary tree traversal. traversal

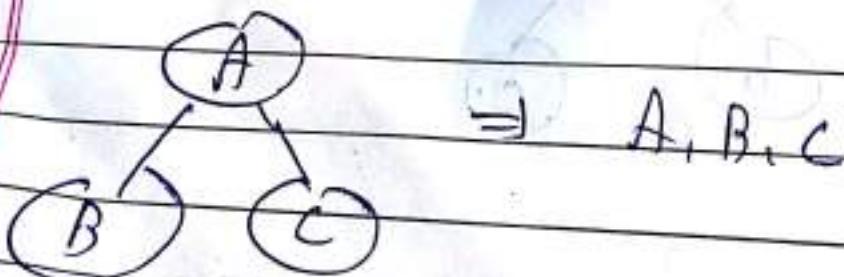

There are three types of binary tree traversal

1. Pre - order Traversal
2. In - order " "
3. Post - order " "

### I. Pre - order Traversal

It is defined as follows:

1. Process the root node
2. traverse the left sub tree
3. traverse the Right sub tree

Post - D, L, R

In - L, D, R

Pre - LRD

Algorithm :

PREORDER(T)

T → pointer for root node

1. [Process the root node]

If T = NULL

then write ("Empty tree")

else

write (DATA (T))

2. [Process the left sub-tree]

left\_ptr

If (LPT(RCT) ≠ NULL )

then call - PREORDER(LPTR)

3. [Process the right sub-tree]

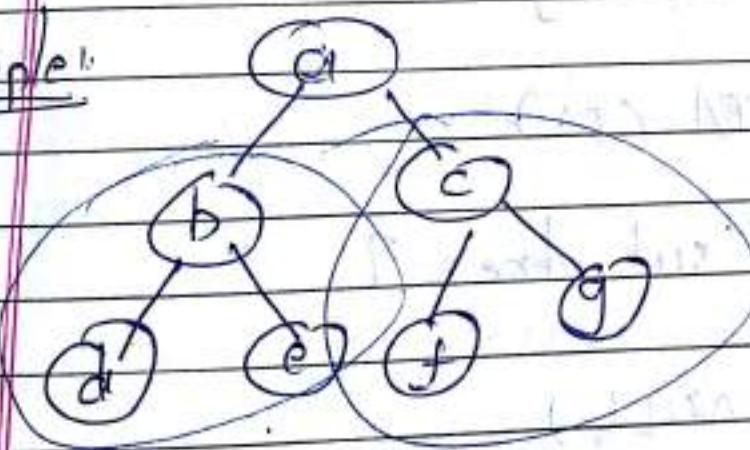

If RPT(RCT) ≠ NULL

then call - PREORDER(RPTR)

4. [Finish]

Return

Example:

a, b, d, e, c, f, g

Inorder traversal:

It is defined as follows:

- traversing the left sub tree
- visiting the root node
- traversing the right sub tree

Algorithm:

INORDER(CT)

1. [Process the root node]

If  $T = \text{null}$   
then write ("Empty tree");

2. [Process the left subtree]

If ( $LPTA(T) \neq \text{NULL}$ )  
then call INORDER ( $LPTA(T)$ )

3. [Process the root node]

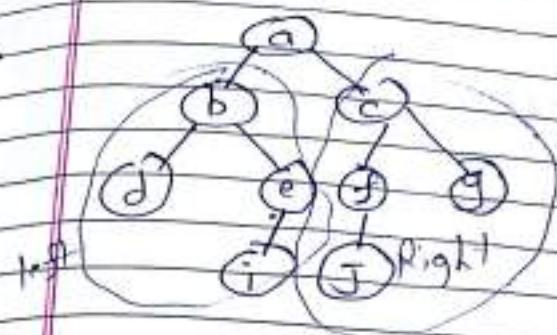

write (DATA (T))

4. [Process the right subtree]

If ( $RPTA(T) \neq \text{NULL}$ )

then call INORDER ( $RPTA(T)$ )

Finish  
Return

d, b, i, e, a, j, f, c, g

### 3. Post-order traversal:

~~root node~~ (last always)

- traversal left sub tree
- " Right " "
- process the root node

### Algorithm:

#### \* POSTORDER(T)

check for empty tree

1. [Process the root node]

if  $T = \text{null}$

then write ("Empty tree");

2. [Process the left subtree]

If ( $LPTR(T) \neq \text{NULL}$ )

then call POSTORDER( $LPTR(T)$ )

3. Process the right subtree.

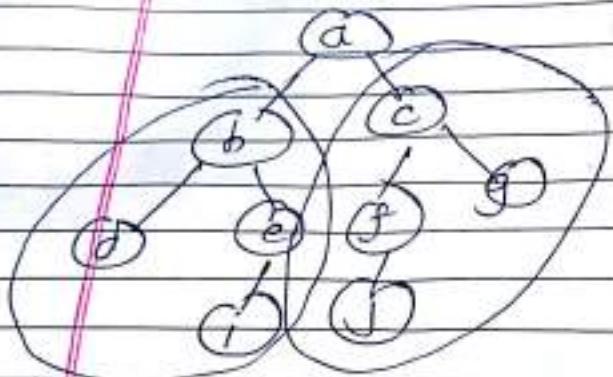

if  $RPTR(T) \neq \text{NULL}$

then call POSTORDER( $RPTR(T)$ )

4. Process the root node  
(write DATA CT)

5. finish

Return

d, i, e, b, j, f, g, c, a
